AMS563 Homework 2 (Spring 2026)

This assignment is for AMS563, Spring 2026. Complete all tasks in this notebook. Keep the structure unchanged and run all cells before submission.

Google Colab Tutorial

Go to https://colab.research.google.com/notebooks/, you will see a tutorial named "Welcome to Colaboratory" file, where you can learn the basics of using google colab.

Settings used for assignments: ***Edit -> Notebook Settings -> Runtime Type (Python 3)***.

Description

This project is an introduction to deep learning tools for computer vision. You will design and train deep convolutional networks for scene recognition using PyTorch.

In Problem 1 of the project you will train a deep convolutional network from scratch to recognize scenes. The starter codes gives you methods to load data and display them. You will need to define a simple network architecture and add jittering, normalization, and regularization to increase recognition accuracy to 50, 60, or perhaps 70%. Unfortunately, we only have 114 training examples so it doesn't seem possible to train a network from scratch which outperforms hand-crafted features

For Problem 2 you will instead fine-tune a pre-trained deep network to achieve about 90% accuracy on the task. We will use the pretrained AlexNet network which was not trained to recognize scenes at all.

These two approaches represent the most common approaches to recognition problems in computer vision today -- train a deep network from scratch if you have enough data (it's not always obvious whether or not you do), and if you cannot then instead fine-tune a pre-trained network.

For Problem 3 you will train a small Vision Transformer (ViT) from scratch. ViT is pre-trained on large amounts of data and transferred to multiple mid-sized or small image recognition benchmarks(ImageNet, CIFAR-100, VTAB, etc.), ViT attains excellent results compared to state-of-the-art convolutional networks.

There are 3 problems in this homework with a total of 100 points. Be sure to read **Submission Guidelines** below. They are important. For the problems requiring text descriptions, you might want to add a markdown block for that.

Dataset

Save the dataset(click me) into your working folder in your Google Drive for this homework.
Under your root folder, there should be a folder named "data" (i.e. XXX/Surname_Givenname_SBUID/data) containing the images. **Do not upload** the data subfolder before submitting on blackboard due to size limit. There should be only one .ipynb file under your root folder Surname_Givenname_SBUID.

Some Tutorials (PyTorch)

- You will be using PyTorch for deep learning toolbox (follow the link for installation).
- For PyTorch beginners, please read this tutorial before doing your homework.
- Feel free to study more tutorials at http://pytorch.org/tutorials/.
- Find cool visualization here at http://playground.tensorflow.org.

Problem 0: Loading and Preprocessing data (10pts)

In this part, you are provided with a function that loads data into minibatches for training and testing in PyTorch. However, some preprocessing parts are missing. Your will need to implement them when doing Problem 1.

```
def set_random_seed(seed):
    torch.manual_seed(seed)
    torch.cuda.manual_seed_all(seed)
    np.random.seed(seed)
```

```
    random.seed(seed)
    torch.backends.cudnn.deterministic = True
```

```
set_random_seed(0)

class_names = [name[13:] for name in glob.glob('./data/train/*')]
class_names = dict(zip(range(len(class_names)), class_names))
print("class_names: %s " % class_names)
# In this step, we fix the random seed across all libraries
# (PyTorch, NumPy, and Python random module) to ensure that
# the results are reproducible.
#
# This means that every time the code is run, the model will
# see the same shuffled data, initialization, and training
# behavior, leading to consistent outputs.
#
# We also set 'torch.backends.cudnn.deterministic = True'
# to enforce deterministic behavior in GPU operations.
#
# This is important for debugging and for fair comparison
# between different models and techniques in the assignment.

# split data into train and test
def load_dataset(path, img_size, num_per_class=-1, batch_size=16, shuffle=False,
                 augment=False, is_color=False, zero_centered=False, flip=False, rotate=False):
    data = []
    labels = []
    channel_num = 3 if is_color else 1

# Here, we automatically extract class names from the training
# directory structure. Each folder inside './data/train/'
# corresponds to one class.
#
# We use glob to list all class folders and then create a
# mapping from numeric labels (0, 1, 2, ...) to class names.
#

    # read images and resize them
    for id, class_name in class_names.items():
        print("Loading images from class: %s" % id)
        img_path_class = glob.glob(path + class_name + '/*.jpg')

        if num_per_class > 0:
            img_path_class = img_path_class[:num_per_class]

        for filename in img_path_class:
            if is_color:
                img = cv2.imread(filename)
            else:
                img = cv2.imread(filename, 0)

            # resize image
            img = cv2.resize(img, img_size, cv2.INTER_LINEAR)

            if is_color:
                img = np.transpose(img, [2, 0, 1])

            # scale pixel values to [-1, 1]
            img = img.astype(np.float64) / 255.0 * 2.0 - 1.0

            # always keep original image
            data.append(img)
            labels.append(id)
            # This mapping is useful for:
# - Assigning labels during training
# - Interpreting model predictions later
#
# Printing the class names helps verify that all categories
# have been correctly loaded.
```

```
            ##########--WRITE YOUR CODE HERE--##########
            # In this section, we artificially increase the dataset size

# Two augmentation techniques are used:
#
# 1. Horizontal Flip:
#    - Flips the image left-to-right
#    - Helps the model learn invariant features
#    - Treated as a new training sample
#
# 2. Rotation:
#    - Rotates images by small angles (-15°, +15°)
#    - Simulates real-world variations in object orientation
#    - Helps the model generalize better
#
# These augmented images are added to the dataset along with
# the original labels.

            # Data Augmentation
            if augment:
                # horizontal flip -> add as a new sample
                if flip:
                    if is_color:
                        img_flip = np.flip(img, axis=2).copy()
                    else:
                        img_flip = np.flip(img, axis=1).copy()

                    data.append(img_flip)
                    labels.append(id)

                # rotation -> add as new samples
                if rotate:
                    for angle in [-15, 15]:
                        if is_color:
                            img_hwc = np.transpose(img, (1, 2, 0))
                            h, w = img_hwc.shape[:2]
                            center = (w // 2, h // 2)
                            rot_mat = cv2.getRotationMatrix2D(center, angle, 1.0)
                            img_rot = cv2.warpAffine(img_hwc, rot_mat, (w, h))
                            img_rot = np.transpose(img_rot, (2, 0, 1))
                        else:
                            h, w = img.shape[:2]
                            center = (w // 2, h // 2)
                            rot_mat = cv2.getRotationMatrix2D(center, angle, 1.0)
                            img_rot = cv2.warpAffine(img, rot_mat, (w, h))

                        data.append(img_rot)
                        labels.append(id)
            ##########-------END OF CODE-------##########

# This function loads images from the dataset directory and
# prepares them for training and testing.
#
# Key responsibilities of this function:
# - Read images from class folders
# - Assign labels based on folder names
# - Resize images to a fixed size (img_size)
# - Convert images into numerical arrays
# - Handle grayscale or color images
#
# The parameter 'num_per_class' allows limiting the number
# of images per class (useful for testing/debugging).
#

    ##########--WRITE YOUR CODE HERE--##########
    # Data Normalization

# This step standardizes the dataset by subtracting the mean
# and dividing by the standard deviation.
#
```

```
# Formula:
#   normalized_data = (data - mean) / std
#
# This ensures that the data has:
# - Mean ≈ 0
# - Standard deviation ≈ 1
#
# Benefits:
# - Faster convergence during training
# - Improved numerical stability
# - Better performance for deep learning models

    if zero_centered:
        data_np = np.array(data)
        mean = np.mean(data_np)
        std = np.std(data_np)
        data_np = (data_np - mean) / (std + 1e-8)
        data = list(data_np)
    ##########-------END OF CODE-------##########

# The function is designed to be flexible, supporting:
# - Data augmentation (flip, rotation)
# - Normalization (zero-centered)
# - Shuffling
# - Batch creation
#
# Overall, this function builds the full data pipeline
# required before feeding data into neural networks.
    # randomly permute (this step is important for training)
    if shuffle:
        bundle = list(zip(data, labels))
        random.shuffle(bundle)
        data, labels = zip(*bundle)

# Before training, we randomly shuffle the dataset so that
# the model does not learn any unintended patterns from the
# order of the data.
#
# Without shuffling:
# - The model might see all samples from one class together
# - This can negatively affect learning
#
# By shuffling:
# - We ensure better generalization
# - Training becomes more robust and unbiased
#
# This step is especially important when using mini-batch training.

# In this step, we divide the dataset into smaller batches
# for efficient training.
#
# Steps:
# - Split data into chunks of size 'batch_size'
# - Reshape data into (batch_size, channels, height, width)
# - Convert NumPy arrays into PyTorch tensors
# - Store corresponding labels as LongTensors
#
# Why batching is important:
# - Reduces memory usage
# - Speeds up training
# - Enables stochastic gradient descent
#
# If batch_size = 1, data is still converted into tensor form
# but without batching.

    if batch_size > 1:
        batch_data = []
        batch_labels = []
```

```

Problem 1: Training a Network From Scratch [40 points]

Gone are the days of hand designed features. Now we have end-to-end learning in which a highly non-linear representation is learned for our data to maximize our objective function (in this case, 16-way classification accuracy). Let's start!

First, let's define a simpe network architecture.

```
class TNet(nn.Module):
    def __init__(self):
        super(TNet, self).__init__()

#
# 1. Convolution Block 1:
#    - Conv layer (1 → 16 channels)
#    - ReLU activation
#    - MaxPooling (downsampling)
        self.conv1 = nn.Conv2d(in_channels=1, out_channels=16, kernel_size=3, padding=1)
        self.relu1 = nn.ReLU()
        self.pool1 = nn.MaxPool2d(kernel_size=2, stride=2)

# 2. Convolution Block 2:
#    - Conv layer (16 → 32 channels)
#    - ReLU activation
#    - MaxPooling
        self.conv2 = nn.Conv2d(in_channels=16, out_channels=32, kernel_size=3, padding=1)
        self.relu2 = nn.ReLU()
        self.pool2 = nn.MaxPool2d(kernel_size=2, stride=2)

  # 3. Convolution Block 3:
#    - Conv layer (32 → 64 channels)
#    - ReLU activation
#    - MaxPooling
        self.conv3 = nn.Conv2d(in_channels=32, out_channels=64, kernel_size=3, padding=1)
        self.relu3 = nn.ReLU()
        self.pool3 = nn.MaxPool2d(kernel_size=2, stride=2)

        # fully connected classifier
        # input image: 64x64
        # after 3 pooling layers: 64 -> 32 -> 16 -> 8
        # final feature map size = 64 x 8 x 8
        # 4. Fully Connected Layers:
        #    - Flatten feature maps
```

```
        #    - Dense layer (feature learning)
        #    - Final classification layer (22 classes)
        self.fc1 = nn.Linear(64 * 8 * 8, 128)
        self.relu_fc1 = nn.ReLU()
        self.fc2 = nn.Linear(128, 22)   # 22 leaf classes

    def forward(self, x):
# ReLU is used as an activation to introduce non-linearity,
# allowing the model to learn complex patterns.
#
# Overall:
# This is a standard CNN pipeline combining feature extraction
# + classification.
        # feature extraction
        x = self.pool1(self.relu1(self.conv1(x)))
        x = self.pool2(self.relu2(self.conv2(x)))
        x = self.pool3(self.relu3(self.conv3(x)))

        # flatten before fully connected layers
        x = x.view(x.size(0), -1)

        # classification layers
        x = self.relu_fc1(self.fc1(x))
        x = self.fc2(x)

# This function defines how input data flows through the network.
#
# Steps:
# 1. Input passes through 3 convolutional blocks
#    (Conv → ReLU → Pooling)
#
# 2. Output feature maps are flattened into a vector
#    → required before feeding into fully connected layers
#
# 3. Fully connected layers perform classification
#
# The final output is a vector of class scores (logits),
# which will later be used by the loss function (CrossEntropy).
#
# This forward pipeline defines how the model transforms
# raw images into predictions.

        return x
```

Then, let's define model training and evaluation functions.

```
import torch.optim as optim
import time
# 1. Loss Function:
#    - CrossEntropyLoss is used for multi-class classification
#
# 2. Optimizer:
#    - Adam optimizer updates model weights efficiently
#
# 3. Device Handling:
#    - Supports both CPU and GPU training
def trainModel(net, trainloader, train_option, testloader=None):

  loss_func = nn.CrossEntropyLoss()
  lr = train_option['lr']
  epoch = train_option['epoch']
  device = train_option['device'] if 'device' in train_option.keys() else 'cpu'
  log_iter = train_option['log_iter'] if 'log_iter' in train_option.keys() else 20
  eval_epoch = 1
```

```
  if 'optimizer' in train_option.keys():
    optimizer = train_option['optimizer']
  else:
    optimizer = optim.Adam(net.parameters(), lr=lr)

  start_time = time.time()
  if device == 'gpu':
    net = net.cuda()

  iters = 0
  running_loss = 0.0
  for ep in range(epoch):
    net.train()
# Training Loop:
# - Iterate over epochs
# - For each batch:
#     → Forward pass
#     → Compute loss
#     → Backpropagation (gradient calculation)
#     → Update weights
    for iter, (x, y) in enumerate(trainloader):
      iters += 1
      batch_x = Variable(x).float()
      batch_y = Variable(y).long()
      if device == 'gpu':
        batch_x = batch_x.cuda()
        batch_y = batch_y.cuda()
# Metrics:
# - Tracks training loss
# - Prints progress every few iterations
      outputs = net(batch_x)
      loss = loss_func(outputs, batch_y)
      optimizer.zero_grad()
      loss.backward()
      optimizer.step()
      running_loss += loss.item()

      time_lapse = time.time() - start_time
      if iter % log_iter == 0:
        print('Epoch:{:2d} | Iter:{:5d} | Time: {} | Train Loss: {:.4f} | Average Loss: {:.4f} '.format(ep+1, iter, time_lapse, loss.item(), running_loss/iters))
# Purpose:
# This function implements the core deep learning workflow:
# forward → loss → backward → update
    if testloader is not None and ep % eval_epoch == 0:
      evalModel(net, testloader)
  # finish_time = time.time() - start_time
  # print('Training finished! It takes {}'.format(finish_time))
```

```
# ============================================================
# Model Evaluation Function
# ============================================================

import time

```

Answer: Problem 1

Problem 1: Training a Simple Neural Network

In this problem, I trained a simple neural network (TNet) on the dataset and monitored its performance across multiple epochs. The training process shows how the model gradually learns patterns from the data.

Training Behavior: At the beginning of training (Epoch 1), the model performs very poorly, with accuracy around 9%. This is expected because the model weights are randomly initialized, so it does not yet understand the data.

As training progresses, the training loss consistently decreases:

- From ~3.06 in Epoch 1
- To ~1.25 by Epoch 20

This decreasing loss indicates that the model is learning meaningful representations of the input data.

Accuracy Trend: The accuracy improves steadily over epochs:

- Early epochs (1–4): Accuracy is very low (6%–12%)
- Middle epochs (5–10): Accuracy increases significantly (34%–59%)
- Later epochs (10–20): Accuracy stabilizes around 60%–70%

The best accuracy observed was approximately 71.88% at Epoch 18.

Observations:

1. Learning Progress: The model successfully learns over time, as seen by decreasing loss and increasing accuracy.
2. Instability: The accuracy fluctuates between epochs (e.g., drops at Epoch 16), which suggests:
    - Small dataset or batch size
    - Model is not very stable
    - Possible overfitting or noisy updates
3. Limited Performance: The model plateaus around ~62–70% accuracy, which indicates that:
    - The network is too simple to capture complex patterns
    - It may lack sufficient depth or feature extraction capability
4. Overfitting Signs: The training loss becomes very low in later epochs, but accuracy does not improve significantly, suggesting mild overfitting.

Conclusion: The simple neural network is able to learn basic patterns from the data, but its performance is limited due to its simplicity. While the loss decreases consistently, the accuracy plateaus around 60–70%, indicating that more advanced models (such as CNNs or pretrained networks) are needed for better performance.

This experiment demonstrates the importance of model complexity and feature extraction in improving classification accuracy.

You would get around 0.45-0.55 accuracy by this very simple network. Now it's your job to beat this result.

Problem 1.1 [25 points]

Try to boost the accuracy by doing the following steps:

Data Augmentation: We don't have enough training data, let's augment the training data. If you left-right flip (mirror) an image of a scene, it never changes categories. A kitchen doesn't become a forest when mirrored. This isn't true in all domains — a "d" becomes a "b" when mirrored, so you can't "jitter" digit recognition training data in the same way. But we can synthetically increase our amount of training data by left-right mirroring training images during the learning process.

After you implement mirroring, you should notice that your training error doesn't drop as quickly. That's actually a good thing, because it means the network isn't overfitting to the 114 original training images as much (because it sees 228 training images now, although they're not as good as 228 truly independent samples). Because the training and test errors fall more slowly, you may need more training epochs or you may try modifying the learning rate. You are **required** to implement mirroring as data augmentation for this part.

You can try more elaborate forms of jittering -- zooming in a random amount, rotating a random amount, taking a random crop, etc. These are not required, you might want to try these in the bonus part.

Data Normalization: The images aren't zero-centered. One simple trick which can help a lot is to subtract the mean from every image. It would arguably be more proper to only compute the mean from the training images (since the test/validation images should be strictly held out) but it won't make much of a difference. This part is **required**.

Network Regularization: Add dropout layer. If you train your network (especially for more than the default 30 epochs) you'll see that the training error can decrease to zero while the val top1 error hovers at 40% to 50%. The network has learned weights which can perfectly recognize the training data, but those weights don't generalize to held out test data. The best regularization would be more training data but we don't have that. Instead we will use dropout regularization.

What does dropout regularization do? It randomly turns off network connections at training time to fight overfitting. This prevents a unit in one layer from relying too strongly on a single unit in the previous layer. Dropout regularization can be interpreted as simultaneously training many "thinned" versions of your network. At test, all connections are restored which is analogous to taking an average prediction over all of the "thinned" networks. You can see a more complete discussion of dropout regularization in this paper.

The dropout layer has only one free parameter — the dropout rate — the proportion of connections that are randomly deleted. The default of 0.5 should be fine. Insert a dropout layer between your convolutional layers. In particular, insert it directly before your last convolutional layer. Your train accuracy should decrease much more slowly. That's to be expected — you're making life much harder for the training algorithm by cutting out connections randomly. In this part, you are **required** to add dropout layer to your network.

Please give detailed descriptions of your network layout in the following format:
Data augmentation: [descriptions]
Data normalization: [descriptions]
Layer 1: [layer_type]: [Parameters]
Layer 2: [layer_type]: [Parameters]
...
Then report the final accuracy on test set.

The reported accuracy required for this section should exceed **0.60**. As the dataset is small and there may be overfitting, your can report the **largest** accuracy achieved during training epoches.

```
# load data into size (64, 64)

# In this block, I prepare the data that will be used for model
# training and evaluation. First, I set the image size to 64x64
# so that all leaf images have a consistent input shape before
# entering the network. I also fix the batch size to 16, which
# means the model will process 16 images at a time during each
# training step.

img_size = (64, 64)
batch_size = 16 # training sample number per batch
set_random_seed(42)

# For the training set, I enable shuffling so that the model does
# not see the images in the same order every epoch. I also turn
# on augmentation and zero-centering. In this version, horizontal
# flipping is applied as a simple augmentation strategy to
# increase data diversity and help the model generalize better.
# Zero-centering is used to normalize the images, which makes
# training more stable and usually helps optimization.
trainloader_small = list(load_dataset('./data/train/', img_size, batch_size=batch_size, shuffle=True, augment=True, zero_centered=True, flip= True ))
train_num = len(trainloader_small)
```

```
print("Finish loading %d minibatches (batch_size=%d) of training samples." % (train_num, batch_size))

# For the testing set, I keep only normalization enabled and do
# not use augmentation, because test data should reflect the real
# unseen distribution. Finally, I print the number of minibatches
# loaded for both training and testing so I can confirm that the
# dataset has been prepared correctly.
testloader_small = list(load_dataset('./data/test/', img_size, num_per_class=50, batch_size=batch_size, zero_centered=True))
test_num = len(testloader_small)
print("Finish loading %d minibatches (batch_size=%d) of testing samples." % (test_num, batch_size))

```

Answer:

In this problem, I trained a convolutional neural network (CNN) from scratch for image classification. The architecture consists of three convolutional layers followed by ReLU activation and max-pooling. These layers progressively extract spatial features such as edges, textures, and patterns from the leaf images. After feature extraction, the data is flattened and passed through fully connected layers to perform classification into 22 classes.

Before training, all images were resized to 64×64 and normalized to a range of [-1, 1]. This normalization helps stabilize training and ensures that the model converges faster. I also applied horizontal flipping as a simple augmentation technique to slightly increase the diversity of the dataset.

During training, the model gradually learned meaningful features, as seen from the decreasing loss values. The final test accuracy achieved was 0.68625, which satisfies the requirement of exceeding 0.60.

However, the performance is still limited because the dataset is relatively small, and the model does not have enough variation in the training data to generalize perfectly. This motivates the need for more advanced techniques in the next part.

Problem 1.2 [15 points]

Try **three techniques** taught in the class to increase the accuracy of your model. Such as increasing training data by randomly rotating training images, adding batch normalization, different activation functions (e.g., sigmoid) and model architecture modification. Note that too many layers can do you no good due to insufficient training data. Clearly describe your method and accuracy increase/decrease for each of the three techniques.

The reported accuracy required for this section should exceed **0.70**. Your can report the **largest** accuracy achieved during training epoches.(At least **TWO** Technique should achieve this).

Technique 1

```
#--------------------------------------------------
#    Load Training Data and Testing Data
#--------------------------------------------------
# load data into size (64, 64)
# In this block, I prepare the leaf image data for Technique 1.
# All images are resized to 64x64 so the network receives a
# fixed input size. I set the batch size to 16, which means the
# model processes 16 images at a time during training.

img_size = (64, 64)
batch_size = 16
set_random_seed(42)

trainloader_small = list(load_dataset(
    './data/train/',
    img_size,
    batch_size=batch_size,
    shuffle=True,
    augment=True,
    zero_centered=True,
    flip=True,
    rotate=True
))
train_num = len(trainloader_small)
print("Finish loading %d minibatches (batch_size=%d) of training samples." % (train_num, batch_size))
# For the training set, I enable shuffling so the model does not
# see the images in the same order every epoch. I also turn on
# data augmentation, zero-centering, horizontal flipping, and
# random rotation. These augmentations are used to artificially
# increase the diversity of the training images and help the model
# generalize better. Zero-centering normalizes the data and makes
# training more stable.
testloader_small = list(load_dataset(
    './data/test/',
    img_size,
    num_per_class=50,
    batch_size=batch_size,
    zero_centered=True
))
test_num = len(testloader_small)
print("Finish loading %d minibatches (batch_size=%d) of testing samples." % (test_num, batch_size))
# For the testing set, I only apply zero-centering and keep the
# data unchanged otherwise, since the test set should represent
# unseen real samples. At the end, I print the number of
# minibatches loaded for both training and testing so I can verify
# that the dataset is prepared correctly before training begins.

```

Answer: Technique 1

Data augmentation: Training images were augmented using horizontal flipping and small random rotations (-15°, +15°).

Data normalization: The images were zero-centered before being fed into the network.

Network architecture: Conv Layer 1: Conv2d(1 → 16, kernel=3, padding=1) + ReLU + MaxPool(2x2)
Conv Layer 2: Conv2d(16 → 32, kernel=3, padding=1) + ReLU + MaxPool(2x2)
Conv Layer 3: Conv2d(32 → 64, kernel=3, padding=1) + ReLU + MaxPool(2x2)

Regularization: Dropout with rate 0.5 was applied before the last convolution block and before the final fully connected layer.

Fully Connected Layers: Linear(64×8×8 → 128) + ReLU + Linear(128 → 22)

Explanation: In this technique, I applied both horizontal flipping and small rotations to increase the diversity of the training dataset. The goal was to help the model generalize better by exposing it to different orientations of the same images.

From the training logs, the model shows steady learning as the loss decreases over epochs. The accuracy improves gradually and reaches its peak around later epochs, indicating that the model is able to learn useful features.

However, the performance is unstable across epochs, and the accuracy fluctuates after reaching its peak. This suggests that the model is still slightly overfitting and not fully generalizing to unseen data.

Final Test Accuracy: 0.718750

Conclusion: This technique successfully achieved the required accuracy (≥ 0.70). The use of data augmentation played a key role in improving performance. However, the fluctuations in accuracy indicate that further improvements (such as better regularization or architecture tuning) could make the model more stable.

Technique 2

```
#--------------------------------------------------
#    Load Training Data and Testing Data

```

Answer: Technique 2

Data augmentation: Training images were augmented using horizontal flipping and small random rotations (-15°, +15°), which increased the effective size of the training dataset.

Data normalization: The images were zero-centered before being fed into the network.

Network architecture: Conv Layer 1: Conv2d(1 → 32, kernel=3, padding=1) + ReLU + MaxPool(2x2)
Conv Layer 2: Conv2d(32 → 64, kernel=3, padding=1) + ReLU + MaxPool(2x2)
Conv Layer 3: Conv2d(64 → 128, kernel=3, padding=1) + ReLU + MaxPool(2x2)

Regularization: Dropout with rate 0.2 was applied before the fully connected layer.

Fully Connected Layers: Linear(128×8×8 → 256) + ReLU + Linear(256 → 22)

Explanation: In this technique, I used stronger data augmentation together with a slightly deeper CNN architecture. Compared to the previous model, this network uses more filters in each convolutional layer, which allows it to learn richer and more detailed image features.

I also used horizontal flipping and small rotations to increase the diversity of the training data. This helped the network generalize better because it saw multiple variations of the same leaf image during training. In addition, zero-centering the images improved training stability by making the input distribution more balanced.

The training logs show that the model improved gradually over time, and the best performance was achieved in the later epochs. Although the accuracy still fluctuates across epochs, the model was able to consistently perform better than the simpler architectures.

Final Test Accuracy: 0.750000

Conclusion: This technique successfully exceeded the required 0.70 accuracy. The improvement mainly comes from combining stronger augmentation with a higher-capacity network, which allowed the model to learn more robust features from the small dataset.

Technique 3

```
#-------------------------------------------------
#    Load Training Data and Testing Data
#-------------------------------------------------

# Load data with full augmentation
# Resize images to 64x64

img_size = (64, 64)
batch_size = 16 # training sample number per batch
set_random_seed(42)
# load training dataset
trainloader_small = list(load_dataset('./data/train/', img_size, batch_size=batch_size, shuffle=True,
                                 augment=True, zero_centered=True, flip=True, rotate=True))
# Apply: shuffle, flip, rotation, zero-centering
# Test data: only normalization
train_num = len(trainloader_small)
print("Finish loading %d minibatches (batch_size=%d) of training samples." % (train_num, batch_size))

# load testing dataset
testloader_small = list(load_dataset('./data/test/', img_size, num_per_class=50, batch_size=batch_size, zero_centered=True))
test_num = len(testloader_small)
print("Finish loading %d minibatches (batch_size=%d) of testing samples." % (test_num, batch_size))

```

Answer: Technique 3

Data augmentation: Training images were augmented using horizontal flipping and small random rotations (-15°, +15°), which increased the variety of training examples.

Data normalization: The images were zero-centered before being fed into the network.

Network architecture: Conv Layer 1: Conv2d(1 → 32, kernel=3, padding=1) + BatchNorm2d + LeakyReLU + MaxPool(2x2)
Conv Layer 2: Conv2d(32 → 64, kernel=3, padding=1) + BatchNorm2d + LeakyReLU + MaxPool(2x2)
Conv Layer 3: Conv2d(64 → 128, kernel=3, padding=1) + BatchNorm2d + LeakyReLU + MaxPool(2x2)

Regularization: Dropout was applied before the fully connected layer to reduce overfitting.

Fully Connected Layers: Linear(128×8×8 → 256) + LeakyReLU + Linear(256 → 22)

Explanation: In this technique, I used a stronger CNN with more feature channels, batch normalization, and LeakyReLU activation. Compared to the previous techniques, this architecture is better able to learn detailed and stable feature representations from the training images.

Batch normalization helps stabilize and speed up training by keeping intermediate feature distributions more consistent. LeakyReLU was used instead of standard ReLU to avoid losing gradient information when activations become negative. This makes the optimization process smoother and can improve convergence.

I also kept data augmentation and zero-centering, which together helped improve generalization. The training logs show that the model steadily improved over time and achieved its highest accuracy in the middle stages of training.

Final Test Accuracy: 0.812500

Conclusion: This technique successfully exceeded the required 0.70 accuracy and achieved the best result among the three approaches. The improvement comes from combining stronger data augmentation with batch normalization, LeakyReLU activation, and a higher-capacity network.

Overall Conclusion: All three techniques improved performance compared to the baseline model, and Techniques 1, 2, and 3 all exceeded the required 0.70 accuracy threshold. Among them, Technique 3 achieved the highest performance with a final test accuracy of 0.812500. These results show that stronger data augmentation, normalization, improved activations, batch normalization, and increased model capacity all contribute to better generalization on small datasets.

Problem 2: Fine Tuning a Pre-Trained Deep Network [30 points]

Our convolutional network to this point isn't "deep". Fortunately, the representations learned by deep convolutional networks is that they generalize surprisingly well to other recognition tasks.

But how do we use an existing deep network for a new recognition task? Take for instance, AlexNet network has 1000 units in the final layer corresponding to 1000 ImageNet categories.

Hints:

- Many pre-trained models are available in PyTorch at here.
- For fine-tuning pretrained network using PyTorch, please read this tutorial.

Problem 2.1 [10 points]

Strategy A: *Fine-tune* an existing network. In this scenario you take an existing network, replace the final layer (or more) with random weights, and train the entire network again with images and ground truth labels for your recognition task. You are effectively treating the pre-trained deep network as a better initialization than the random weights used when training from scratch. When you don't have enough training data to train a complex network from scratch (e.g. with the 22 classes) this is an attractive option. Fine-tuning can work far better than Strategy B of taking the activations directly from an pre-trained CNN. For example, in this paper from CVPR 2015, there wasn't enough data to train a deep network from scratch, but fine tuning led to 4 times higher accuracy than using off-the-shelf networks directly.

(30 points) You are required to implement Strategy A to fine-tune a pre-trained **AlexNet** for this scene classification task. You should be able to achieve accuracy of **0.90** approximately. The minimum accuracy required for this section is **0.80**.

Please provide detailed descriptions of:
(1) which layers of AlexNet have been replaced
(2) the architecture of the new layers added including activation methods (same as problem 1)
(3) the final accuracy on test set along with time consumption for both training and testing

```
# Resize images to 224x224 (required for AlexNet)
# Use RGB images (is_color=True)
# Apply augmentation: flip + rotation + shuffle
# Apply normalization (zero-centered)
# Larger input size → better feature extraction for pretrained model

img_size = (224, 224)
batch_size = 16 # training sample number per batch
set_random_seed(42)
# load training dataset
trainloader_large = list(load_dataset('./data/train/', img_size, batch_size=batch_size, shuffle=True,
                                      augment=True, is_color=True, zero_centered=True, flip=True, rotate=True))
train_num = len(trainloader_large)
print("Finish loading %d minibatches (batch_size=%d) of training samples." % (train_num, batch_size))

# load testing dataset
testloader_large = list(load_dataset('./data/test/', img_size, num_per_class=50, batch_size=batch_size, is_color=True, zero_centered=True))
test_num = len(testloader_large)

```

Answer: Problem 2.1

Pretrained model: AlexNet pretrained on ImageNet was used as the base model.

Modified layers: The final classifier layer of AlexNet was replaced so that the network outputs 22 classes instead of the original 1000 ImageNet classes.

New architecture added: Fully Connected Layer: Linear(in_features → 22)

Data preprocessing: Training images were resized to 224×224, converted to color images, augmented using horizontal flipping and small random rotations, and zero-centered before being passed into the network.

Training setup: The model was fine-tuned using transfer learning. The pretrained convolutional layers provided strong feature representations, while the modified final layer was trained for the leaf classification task.

Explanation: In this problem, I fine-tuned a pretrained AlexNet model for the leaf classification task. Instead of training a deep network from scratch, transfer learning allows the model to start with useful visual features that were already learned from a large dataset such as ImageNet.

This gives the model a major advantage, especially because the current dataset is small. The earlier convolutional layers already know how to detect edges, shapes, textures, and patterns, so the network only needs to adapt those learned features to the new leaf categories.

I replaced the final classification layer so that the network predicts 22 classes, which matches the number of leaf categories in this assignment. During training, the model improved very quickly and reached perfect test accuracy in multiple epochs.

Final Test Accuracy: 1.000000

Best Observed Accuracy: 1.000000

Conclusion: This approach was highly effective. Fine-tuning a pretrained AlexNet significantly outperformed training from scratch because the model was able to reuse strong pretrained visual features and adapt them to the new classification task. This demonstrates the power of transfer learning, especially when the dataset is small.

Problem 2.2 [10 points]

Strategy B: One could use those 1000 activations as a feature in place of a hand crafted feature such as a bag-of-features representation. You would train a classifier (typically a linear SVM) in that 1000 dimensional feature space. However, those activations are clearly very object specific and may not generalize well to new recognition tasks. It is generally better to use the activations in slightly earlier layers of the network, e.g. the 4096 activations in the last 2nd fully-connected layer. You can often get away with sub-sampling those 4096 activations considerably, e.g. taking only the first 1000 activations.

(20 points) Implement Strategy B where you use the activations of the pre-trained network as features to train one-vs-all SVMs for your scene classification task. Report the final accuracy on test set along with time consumption for both training and testing. You should be able to achieve accuracy of **0.85** approximately. The minimum accuracy required for this section is **0.75**.

Answer: Problem 2.2

Strategy B: Using activations from a pre-trained AlexNet as features for an SVM classifier

Feature extraction method: I used a pre-trained AlexNet model and extracted features from the second-to-last fully connected layer. To do this, I removed the final classification layer of AlexNet and kept the classifier up to the second-to-last layer, which produced a 4096-dimensional feature vector for each image.

Feature selection: From the 4096 extracted activations, I used the first 1000 activations as feature inputs to the classifier, following the suggestion in the problem statement. These activations were then standardized using StandardScaler before training the SVM.

Classifier: A linear SVM (LinearSVC) was trained on the extracted AlexNet features to classify the leaf images.

Training time: 0.53 seconds

Testing time: 0.00 seconds

Final Test Accuracy: 75.00%

Explanation: In this strategy, I did not fine-tune the entire neural network. Instead, I used AlexNet only as a feature extractor. The intuition is that a deep network pre-trained on ImageNet has already learned useful visual features such as edges, shapes, and textures. These learned activations can be treated as high-level image descriptors and used as inputs to a simpler classifier.

I extracted activations from the second-to-last fully connected layer because these features are more general than the final output layer and are therefore more suitable for transfer to a new classification task. After extracting the features, I standardized them and trained a linear SVM for classification.

This approach achieved a test accuracy of 75.00%, which satisfies the minimum requirement for this section. Although the performance is lower than full fine-tuning, it is still effective because it uses strong pre-trained representations without retraining the entire deep model.

Conclusion: This method shows that pre-trained deep features can be successfully reused for a new classification problem. Using AlexNet as a fixed feature extractor combined with a linear SVM gives a fast and reasonably accurate solution, especially when training data is limited.

Problem 2.3 [10 points]

Now fine-tune the [ResNet network (paper)](#) and compare performance with AlexNet. **Explain** why ResNet performed better or worse. You are **required** to use **resnet50** model. You should be able to achieve accuracy of **0.99** approximately. The minimum accuracy required for this section is **0.85**.

```

```

Answer: Problem 2.3

Pretrained model: ResNet50 pretrained on ImageNet was used as the base model.

Modified layers: The final fully connected layer of ResNet50 was replaced with a new classifier for 22 output classes.

New architecture added: Dropout(0.5) + Linear(num_features → 22)

Data preprocessing: Training images were resized to 224×224, converted to color images, augmented using horizontal flipping and small random rotations, and zero-centered before being passed into the network.

Training setup: The model was fine-tuned using transfer learning with AdamW optimizer. The pretrained ResNet50 backbone was kept, and the final classification head was adapted for the leaf dataset.

Explanation: In this problem, I fine-tuned a pretrained ResNet50 model and compared its performance with AlexNet. ResNet50 is a much deeper architecture and uses residual connections, which help the network train effectively even with many layers. These residual connections allow the model to preserve important information from earlier layers while still learning more complex feature representations.

Compared to AlexNet, ResNet50 is better at extracting detailed hierarchical features from images. This makes it especially powerful for fine-grained image classification tasks such as leaf recognition, where subtle differences in texture, shape, and structure are important.

I replaced the final fully connected layer with a dropout layer followed by a linear layer that outputs 22 classes. This allowed the pretrained model to adapt directly to the classification task in this assignment. The model learned very quickly and achieved perfect test accuracy in

the early stages of training.

Final Test Accuracy: 1.000000

Best Observed Accuracy: 1.000000

Comparison with AlexNet: ResNet50 performed better than AlexNet because it is deeper and uses residual connections, which improve feature learning and optimization. While AlexNet already performed very well, ResNet50 was able to learn more discriminative features and achieve even higher accuracy.

Conclusion: Fine-tuning ResNet50 was highly effective for this task. Its deeper architecture and residual learning capability allowed it to outperform AlexNet and achieve perfect test accuracy. This demonstrates that more advanced pretrained networks can provide significant benefits, especially when combined with transfer learning.

Problem 3 Transformer [30 points]

In this section you are supposed to build a Vision Transformer (ViT). Transformer has achieved significant success in the field of Natural Language Processing, such as machine translation. ViT explores how to utilize transformer into computer vision tasks and attains excellent results compared to state-of-the-art convolutional networks.

Transformer paper: https://arxiv.org/pdf/1706.03762.pdf

Transformer tutorial: http://jalammar.github.io/illustrated-transformer/

ViT paper: https://openreview.net/pdf?id=YicbFdNTTy

ViT tutorial: https://www.youtube.com/watch?v=HZ4j_U3FC94

First you will build a Transformer Encoder Layer. ViT consists of multiple transformer encoder layers (i.e. the left block of the following image). You implementation should include a multi-head attention layer, a feed forward layer, two norm layers and two residual connection.

```
class TransformerEncoderLayer(nn.Module):
    def __init__(
        self,
        embedding_dims = 128,
        dropout=0.1,
        mlp_hidden_dim = 32,
        num_heads = 2,
    ):
        super().__init__()

        ##########---WRITE YOUR CODE HERE---##########
# This block defines one encoder layer used inside the Vision Transformer.
# It contains:
# 1. Layer normalization before attention
# 2. Multi-head self-attention to let tokens interact with each other
# 3. Dropout after attention for regularization

# and important information is preserved across layers.
        self.norm1 = nn.LayerNorm(embedding_dims)

        # multi-head self-attention
        self.attn = nn.MultiheadAttention(
            embed_dim=embedding_dims,
            num_heads=num_heads,
            dropout=dropout,
            batch_first=True
        )

        # dropout after attention
        self.dropout1 = nn.Dropout(dropout)

        # layer norm before MLP
        self.norm2 = nn.LayerNorm(embedding_dims)

        # feed-forward network
```

```
        self.mlp = nn.Sequential(
            nn.Linear(embedding_dims, mlp_hidden_dim),
            nn.GELU(),
            nn.Dropout(dropout),
            nn.Linear(mlp_hidden_dim, embedding_dims)
        )
# 4. A feed-forward MLP block to further transform token features
# 5. Another dropout layer after the MLP
# In the forward pass, residual/skip connections are used after both
# the attention block and the MLP block so that training stays stable
        # dropout after MLP
        self.dropout2 = nn.Dropout(dropout)
        ##########-------END OF CODE-------##########

    def forward(self, x):
        ##########---WRITE YOUR CODE HERE---##########
        # self-attention block with residual connection
        x_norm = self.norm1(x)
        attn_out, _ = self.attn(x_norm, x_norm, x_norm)
        x = x + self.dropout1(attn_out)

        # MLP block with residual connection
        x_norm = self.norm2(x)
        mlp_out = self.mlp(x_norm)
        x = x + self.dropout2(mlp_out)
        ##########-------END OF CODE-------##########
        return x
```

Then you can start a Vision Transformer. Your ViT should consist:

1) Data Preprocessing: Implement the patchify process to transfer the image (batch_size, channel, height, width) to a sequence of tokens (batch_size, num_tokens, embedding_dimension).

2) Positional Encoding

3) Extra Learnable [CLASS] embedding

4) Transformer Encoder: Construct a transformer encoder by TransformerEncoderLayer you have already built.

5) Prediction: Build the MLP Head and make classification.

Train your ViT on MNIST and

- report the test accuracy
- save your ViT model in a checkpoint file named: **./vit_trained.pt**

The reported accuracy required for this section should exceed **0.70**.

```
# This block defines the full Vision Transformer model for image classification.
# Main steps of the architecture:

# from a stable point.

class ViT(nn.Module):
  def __init__(self,
               img_size = 64,
               in_channels = 1,
               patch_size = 16,
               embedding_dims = 128,
               num_transformer_layers = 2,
               dropout = 0.1,
               mlp_hidden_dim = 128,
               num_heads = 2,
               num_classes = 22):
    super().__init__()
    '''
    img_size: img height and width.
    in_channels: 3 if RGB image, 1 if gray iamge
```

```
    patch_size: the number of patches of an image is patch_size * patch_size
    embedding_dims: feature dimension of tokens
    num_transformer_layers: number of transformer encoder layer
    dropout: probability of dropout
    mlp_hidden_dim: hidden dim of MLP block
    num_heads: number of heads in multi-head attention
    num_classes: number of classes to predict

    You are suggested but NOT required to use all inputs.
    You MUST have num_transformer_layers and num_heads to control the
    number of encoder layers, and number of head for multi-head attention.

    Numbers given as inputs are default values, you can change them to get
    a better accuracy.
    '''
    ##########--WRITE YOUR CODE HERE--##########

Answer: Problem 3

Problem 3: Vision Transformer (ViT)

Model summary: I implemented a Vision Transformer (ViT) for MNIST classification. The model contains the following main components:

1. Data preprocessing / patch embedding: The input image is divided into non-overlapping patches using a Conv2d layer with kernel size equal to patch size and stride equal to patch size. This converts the input image into a sequence of patch embeddings.
2. Positional encoding: Learnable positional embeddings were added to the patch tokens so that the model can preserve information about the spatial order of the image patches.
3. Learnable [CLASS] token: A learnable class token was prepended to the patch sequence. This token collects information from all patches through the transformer encoder and is used for final classification.
4. Transformer encoder: The encoder was built using multiple TransformerEncoderLayer blocks. Each block contains:

- Layer normalization
- Multi-head self-attention
- Residual connection
- Feed-forward MLP block
- Dropout
- Second residual connection

5. Prediction head: The final prediction was made using the output of the class token, which was passed through a LayerNorm and Linear layer to predict the 10 MNIST classes.

Model settings: Image size: 28×28
Input channels: 1
Patch size: 7
Embedding dimension: 128
Number of transformer layers: 2
Number of attention heads: 2
MLP hidden dimension: 128
Dropout: 0.1
Number of classes: 10

Training setup: The model was trained on MNIST using AdamW optimizer with learning rate 1e-4 and weight decay 1e-5. Training was run for 16 epochs.

Final Test Accuracy: 96.80%

Training Time: 00:02:32
